

# Chapter 16.

## Internationalization of production, trade and innovation in the Czech Republic

*Anna Kadeřábková and Marek Rojíček*

### 16.1. Introduction

Due to its external openness, Czech economy has been getting more involved in the globalization process that is characterized by an increase in the mobility of production factors, including technology knowledge.<sup>1</sup> The paper looks into details of the structural characteristics of quality-based competitive advantage from the perspective of industries, trade flows, foreign direct investment activities, and regions. As for industry-related competitive advantage and economic structure, attention is given to performance in terms of technology and knowledge intensities. The industry level is also exploited in the assessment of key characteristics of innovation activities of Czech companies, with a special attention focused on the differences between manufacturing and services (innovation modes, R&D intensity, cost structure and innovation intensity, results, motivation and barriers of innovation activities). In terms of foreign direct investment, attention is especially given to its role in domestic R&D activities (their share in expenditure and employment) and in innovation outputs (in comparison with local companies). At the regional level, focus is aimed at assessing economic performance as both a prerequisite for and results of competitiveness, with a special regard to innovation performance evaluated in terms of R&D activities, technology-intensive value added and the level of foreign direct investment.<sup>2</sup>

---

<sup>1</sup> The underlying research has been supported by the Grant Agency and Ministry of Education of the Czech Republic.

<sup>2</sup> For the survey of key theoretical starting points related to the knowledge-based competitiveness see e.g. Kaderabkova (2004, 2005, 2006), Kaderabkova *et al.* (2006), Rojicek (2006), WEF (2006), UNCTAD (2005, 2006). The comprehensive empirical background has been presented

## 16.2. Structural characteristics of globalization

The nature of global economic activity has a significant impact on the increasing mobility and range of migrating **production factors** that increasingly include, besides industrial production and physical capital, the flows of services, R&D, and human capital that result in flows of skilled workforce and investment in technology and expertise. Together with the changing technology, production, investment and trade flows, the share of **emerging** markets in the global output has been increasing. By 2015, China will have become the second strongest world economy, with India increasing its economic power as well. Production factors will always be directed into the countries with the highest economic or social return that is dependent on their structural characteristics – i.e. the quality of physical and human capital, market size, growth potential, transport costs, and barriers preventing the entry. The current emerging economies show a **high production** in skilled human capital and R&D expenditure (although from a significantly lower base when compared to developed countries). Therefore, in the not so far future, these countries will be, due to their strengthening domestic knowledge base, able to compete against more developed countries in a **wide range of products**, i.e. not only in low value added segments of products and services, where their production costs are markedly lower.

### 16.2.1. Foreign direct investment

Since the 90s, the development of global economy has been characterized by foreign direct investment flows growing faster than world trade. Even though the position of the developed countries, i.e. the USA and EU, remains most important, the share of **emerging markets** has quickly become more significant (China's share went up from 2% in 1990 to 10% in 2004). Unlike in the past, they are not used just as locations for cheap production but they also attract an ever increasing share of investment in **high-quality activities**, i.e. research, development and innovation activities. Together with the growing importance of trade and services, also the importance of FDI has been increasing in this sector. Foreign companies play a bigger role in the R&D performance in the host economies. FDI is important for the **parent company** since they provide for a more efficient production, access to new markets and adoption of new technology. From the macroeconomic perspective, FDI helps restructure economies according to the changing comparative advantage. The majority of FDI from EU countries go to the OECD countries, but the share of emerging economies

---

above all in the annual survey publications of OECD (2005, 2005a, 2006, 2006a). Methodology of innovation performance analysis has been included e.g. in the papers of Arundel, Hollanders (2005) underlying the publication of Innovation Scoreboard.

increases as well. Differences in the FDI development are also apparent within the EU, with the old EU countries losing FDI in favour of the new members.

### 16.3. International division of labour

The growth of trade flows as a result of globalization has initiated a discussion on the impacts of **international division of labour and production**. An increasingly important role of emerging markets (especially India and China) in EU trade stresses the differences in the relative factor endowment among trade partners. These differences subsequently influence industry specialization, thus affecting the labour and investment demand in the individual member states.<sup>3</sup> Specific attention is given to the influence of globalization on individual industries within the EU and on the demand for groups of (differently skilled) employees and to the ability of the qualification supply to react to the changes in the qualification demand structure.

#### 16.3.1. International context

Developed countries have steadily shown a long-term growth of trade openness (the share of trade in GDP). A new trend is presented by the growth of **inter-industry trade** within the EU from the beginning of the new millennium (and since 1996 in the U.S.) that was significantly decreasing in the previous period.<sup>4</sup> This is in part due to the increased importance of trade in raw materials (esp. oil imports) but this trend also significantly impacts manufacturing. The change is attributed especially to the increased importance of trade among countries with different factor endowments, i.e. with different levels of economic development and, subsequently, trade specialization. The available empirical studies have shown so far that the fears of globalization negatively affecting the labour market are groundless – the impact on the total employment seems to have the opposite effect. However, the impact on particular industries or skills should be examined, particularly in combination with their regional concentration.

---

<sup>3</sup> Differences in factor endowment mean that more developed countries show a relative redundant supply of quality-intensive factors – such as skilled workforce, high-technology – with the less developed countries tending to provide cheaper and less skilled workers and adapted, less demanding technology. Factor endowment thus directs industry specialization of production or competitive advantage of a particular country toward high or low tech products (economic activities).

<sup>4</sup> Inter-industry trade is carried out among different industries. The opposite is the intra-industry trade when products are traded within the same industry (commodity group), either as final products (horizontal or vertical IIT) or in different processing stages (vertical IIT).

In comparison to intra-industry trade, the development of inter-industry trade may be connected to higher adjustment costs incurred as a result of the affected industries within the EU losing their comparative advantage. The increased trade importance of China and India and the related change in industry specialization of their comparative advantage provokes fears in developed countries of decreased demand for **less skilled labour force**, followed by an increase in the unemployment rate of this particular group and a decrease in relative wages (increased income inequality). These fears may be substantiated in companies that relocate their activities to cheaper locations using to a large extent unskilled labour force (outsourcing), e.g. assembly of parts, and, on the other side, increase the extent of activities performed by skilled employees (technology development and design). Nevertheless, from a long-term perspective, it may be expected that Chinese technology level will improve and this may result in a repeated change in the nature of trade with the EU countries, shifting from traditional (labour-intensive) products toward technology more sophisticated segments (in EU imports, the share of these segments has already increased significantly over the past five years).<sup>5</sup>

However, the impacts of globalization on the labour market need to be examined in a more comprehensive way, taking into account **static and dynamic effects** of the specialization development in the EU and its current less developed trade partners (including the linkages among these effects). The decrease in the demand for less skilled labour in manufacturing in the EU may be softened by its growth in the non-tradable sector (i.e. services). An important improvement in the educational attainment in developing countries may change the focus of their specialization (the sources of comparative advantage) in favour of quality more intensive activities. On the other hand, a higher external openness increases competition, supporting innovation performance. New technology requires higher skills, thus lowering the demand for less skilled labour. It also needs to be considered that among the various EU countries, there are significant **(structural) differences** in the labour market characteristics that may make the identification of globalization impact on unemployment and wages (groups with different qualification levels) more difficult. Nevertheless, this identification is necessary for corresponding adjustment of the related policies that condition their effectiveness. Initially, the position of Czech economy is assessed accord-

---

<sup>5</sup> The increase in the share of office equipment, telecommunication appliances, electric and electronic instruments in the total Chinese export is a result of a strong FDI inflow in the development of capital and technology intensive industries over the past five years. The main reason for this development is the transfer of the final (labour-intensive) stage from developed countries, with Chinese value added remaining relatively low. The increasing level of the local knowledge base in combination with a high FDI inflow will significantly speed up technology transfer; support the development of internal innovation capacities, thus contributing to narrowing the Chinese technology gap.

ing to the structure and competitive advantage of foreign trade in respect to the position within the EU market, geographic concentration, industry specialisation, and quality characteristics of technology and factor intensities. A special attention is given to the influence of foreign investment on the position of Czech economy within the multinational value chain.

### 16.3.2. The structure and competitiveness of foreign trade

After the EU accession, the foreign **exchange of goods** in all the new members in Central and Eastern Europe became more intensive. However, the Czech Republic was the only country that had a positive trade balance in 2005. Also significant was the shift in the competitiveness reflected in the increased share of Czech exports in EU-25 imports – reaching up to 2.6% compared to 1.5% in 1999. Rather than the actual EU accession itself, the international trade in the Czech Republic was more influenced by long-term structural changes related to the former FDI inflows with significant export-enhancing focus. FDIs also negatively affect the trade balance by importing investment goods and production components. In general, in the first stage of FDI, the pro-import influence is predominant, with exports growing gradually afterwards. In many cases, local manufacturers replace foreign component imports, which further soften the influence of FDI on imports. Currently, the main investment importing stage has ended and the pro-export effect starts to become apparent.

### 16.3.3. Quality of trade structure

In terms of competitiveness within the global market, the position of any given country in the international trade needs to be considered, i.e. the **quality intensity of the value chain**. Comparative advantages and specializations of national economies have been traditionally perceived in terms of trade in final products or industry focus of exports. However, **territorial fragmentation** enables to locate production according to factor intensities of individual stages of the production chain rather than the average factor intensities of the final products. Due to their comparative advantage in the production of labour- or material-intensive components or the assembly of final products, less developed countries may therefore get more intensively involved in the international division of labour even when it comes to producing high-tech products. From 1995, the export structure of new (more developed) EU members shifted strongly in favour of **medium-high-tech** industries. This applies mostly to engineering, electric technologies and the production of transport vehicles. These industries are able to compete in quality as documented by the current growth of export prices and the EU-15 market share (see e.g. Landesmann, Wörz, 2006).

The characteristics of specialization and geographic focus of trade linked to the intensity of integration into the multinational value chain have an important effect on the development of **intra-industry trade** (see table 16.1). Within the multinational chain, products in different production stages are exchanged within the same industry. An increase in the intra-industry trade in manufacturing between 1995 and 2002 is apparent in the majority EU countries. In the Czech Republic, the major increase was recorded in high-tech industries, especially in the production of office equipment. On the other hand, the intra-industry trade in medium-high-tech industries was already high in 1995, and subsequently tended to decrease gradually.

**Table 16.1. The development of share of intra-industry trade in manufacturing**

	1995	1996	1997	1998	1999	2000	2001	2002
HU	75.0	73.1	78.1	77.0	75.8	78.2	80.6	83.8
CZ	74.1	79.7	80.6	82.3	80.1	79.5	81.5	83.3
SK	..	..	74.9	75.3	75.5	74.3	77.2	78.2
PL	62.4	61.4	61.0	60.4	61.4	68.5	72.0	74.1

Note: The share of inter-industry trade may be expressed as the difference between the above number and 100%

Source: OECD, STAN Database (18.7.2006), own calculations.

Comparative industry advantage may be expressed as a **contribution to trade balance**, where it is perceived as a net trade concept (including imports), see table 16.2. In this concept, the total trade deficit is divided among commodities based on their share in the trade total. In 2002, the highest contribution in the Czech Republic came from the group of medium-high-tech industries, especially the automotive industry (its contribution is the highest of all industries). Between 1995 and 2002, the contribution of high-tech industries to trade balance relatively grew, yet it still remained negative, as was the case in the majority of EU countries (with the worst results in the production of TVs, radio and pharmaceutical products).

Between 1995 and 2002, the **share of manufacturing export and import** (relative trade balance) grew in the Czech Republic from 86% to 100%. This share is the highest in medium-high-tech industries, especially in machinery and transport vehicles. In these industries, the Czech Republic and Hungary have the highest export-import ratio of EU countries. Between 1995 and 2002, the share of high-tech industries in the Czech Republic grew considerably, from 20% up to 71%. However, the position of the CR is not as strong as the one of e.g. Ireland, where exports exceed imports more than twice.

**Table 16.2. Indicators of comparative advantage of the Czech Republic in terms of technology intensity**

	HT		MHT		MLT		LT	
	1995	2002	1995	2002	1995	2002	1995	2002
Contr. to trade balance	-6.6	-3.0	-2.7	2.2	5.2	0.2	4.1	0.6
Export/import ratio	20.1	71.2	75.0	111.0	127.9	101.4	123.8	106.8

Note: Technology intensity in manufacturing: HT – high, MHT – medium-high, MLT – medium-low, LT – low.

Between 1995 and 2004, the relative trade to production indicators in the Czech Republic were growing (see table 16.3). This applies to both the share of export in production and the **import penetration** indicator. The share of export in production of the domestic manufacturing grew from 41% to 60%. Similarly, the import penetration grew from 44% to 59%. While the export/production ratio shows the importance of foreign trade for a given industry, the import penetration indicator expresses the share of imports in domestic demand, thus reflecting the competitiveness of local products against imported goods.

The highest share of export in production in high-tech industries was recorded in 2004, reaching 90% in high-tech and 78% in medium-high-tech industries. Since 1995, the ratio has grown by 33 and 21 percentage points respectively, indicating a high increase in the importance of foreign markets for high-tech industries. The share of import in domestic demand for high-tech products between 1995 and 2004 grew from 79% to 91%. It also grew similarly in all other industries. When looking into details of individual industries with medium-high and high technology intensity, it is apparent that office equipment and machinery have the highest share of production for export (almost 100%).

On the contrary, the share of production for export in low-tech industries is significantly lower when compared to high-tech industries. This is most apparent in the food industry, reaching approximately 15%. When compared internationally, the share of export in production for manufacturing in the Czech Republic was relatively high in 2004, significantly above the EU average. This share was higher in almost all industries, with the relatively highest difference in comparison to the EU average in medium-high-tech industries and engineering in particular.

#### 16.3.4. Technology intensity of trade

The analysis of trade in terms of technology intensity shows whether individual industries and their groups and the economy as a whole tend to import medium-low-tech products that are then transformed into products with a higher technology intensity or vice versa.<sup>6</sup> Figure 16.1 shows that high-tech products have the highest share in high-tech industry imports (more than 80%). This share is the highest for office equipment and computers, reaching approximately 95%, and

---

<sup>6</sup> For the analytical purposes, year 2003 was chosen since the product import and export matrixes structured according to industry and commodity classifications are available. It is the last year when the data from customs statistics were collected. After the Czech entry into the EU, the method of data collection has changed from customs declarations to statistic surveys. Even though the quality of data according to commodity classification remains quite high, the data concerning imports and exports for individual industries lose their documentary value as a result of a massive increase in indirect imports and exports (i.e. transactions through intermediaries).

the lowest for the pharmaceutical industry (approximately 50%). Additionally, these industries are known for their high import intensity of exports, exceeding 100% for some industries (this indicator is again lower for the pharmaceutical industry). The import to export ratio exceeding 100% may be caused by distorted prices during trading, a higher share of indirect exports or by import of investment goods.

When looking at the **detailed structure** of high-tech imports, the high share of assembly activities with very low domestic value added is clearly apparent. The high import-intensity of exports also means that even strong export performance of the given industries has basically no influence on the improvement of trade balance. Within the group of **medium high-tech industries**, the core of the Czech manufacturing, medium-high-tech products represent three quarters of imports, and 20% of imports fall in the medium-low and low-tech product category. The import intensity is lower than in the case of high-tech products (71% on average). The highest share of medium-low-tech products in exports, almost one quarter, is represented by the automotive industry. Therefore, this industry is located in a **higher stage** of the value chain. The import intensity of exports reaches only 67%. The automotive production has (in comparison to the volume of foreign trade) significantly positive influence on the trade balance total.

**Figure 16.1. Imports by technology intensity in the CR (2003, in bn. CZK)**

Note: HT = high-technology intensity, MHT = medium-high-tech, MLT = medium-low tech, LT = low-tech.

Source: CZSO, Database of foreign trade (1.10.2006), own calculations.

The **product approach** provides a more detailed analysis of the importance of high-tech industries in foreign trade. It defines technology intensive industries by three to five-digit codes of the SITC classification. As is apparent from the table 16.4, between 1999 and 2003, the share of high-tech products in total exports almost doubled from 6.4% to 12.4%, followed by a slight decrease in 2004.

IT exports increased tenfold, i.e. most significantly. Electronics and telecommunications were the second most important group of exported products, with approximately a quadruple increase. The imports of high-tech products were growing more slowly and their share in the total goods imported grew from 12.4% to only 15.9% between 1999 and 2003. In 2004, similarly to exports, this share slightly decreased. The largest group of high-tech products is represented by electronics and telecommunications, followed by information technology (6.4% and 4.7% respectively of the imported goods total in 2003). Approximately one-half of the high-tech product value includes the processing trade in 2003. This means that the assembly took place in the Czech Republic and the completed products were reexported. This applies mainly to electronic parts and information technologies.

**Table 16.4. Export and import of high-tech products in the Czech Republic - direct and indirect (processing) trade shares (%)**

	Export				Import			
	Direct		Indirect		Direct		Indirect	
	1999	2004	1999	2003	1999	2004	1999	2003
Total high-tech	6.4	12.1	4.8	94.1	12.4	15.1	22.8	49.7
Aerospace	0.36	0.25	0.6	91.4	0.62	0.34	5.3	5.0
Comp., office equipm.	0.87	6.02	1.6	93.6	2.84	4.78	16.5	51.9
Electr., telecommun.	1.26	3.22	2.7	131.4*	4.24	5.82	32.6	76.6
Pharmacy	0.26	0.15	0.0	8.1	0.84	0.69	0.1	0.3
Scientific instruments	0.51	0.83	7.6	61.5	1.32	1.38	31.1	17.9
Electrical machinery	1.50	0.77	0.2	83.7	0.58	0.63	64.9	50.6
Chemistry	0.38	0.19	0.1	2.2	0.68	0.72	12.1	6.9
Non-electrical machin.	0.98	0.58	20.1	25.8	1.19	0.68	5.3	5.2
Armament	0.31	0.13	5.3	0.9	0.06	0.06	5.7	0.8

Note: \* Shares of high-tech trade in total trade, shares of high-tech indirect trade in direct trade. Data on the total exports and exports after processing are not consistent. Source: CZSO, Database of foreign trade (1.11.2005), own calculations.

#### 16.4. Internationalization of research and development

The benefits of FDI to the host economy and their role in economic and technology catch-ups may be differentiated as exogenous (short-term) and exogenous (medium to long-term). **Exogenous benefits** include transfers (improved and redirected production processes, new equipment and machinery, new products, capital imports, new production methods, new corporate functionalities) related to localized effects for foreign affiliates (an improved linkage between the costs

and quality of products, increased production factor efficiency, accelerated upgrading and restructuring). The subsequent development stage brings about **endogenous impacts** in terms of adoption of the knowledge transferred from the parent company to the foreign affiliates (technology, know-how, best practices) and diffusion of new processes and knowledge spillovers into the local companies. There are also indirect effects in the host economy (development of more complex activities with higher value added) as well as direct effects (vertical links to local suppliers and other producers, increased level of spillovers and diffusion of new processes). The extent and intensity of spillovers are decisively influenced by the prevailing type of innovation strategies in the foreign affiliates especially distinctive in terms of motivation and intensity of internal research activities (see UNCTAD, 2006).

#### 16.4.1. International context

New EU members attract an increasing amount of investment in activities intensive in **higher skills** (e.g. precision engineering, design, research and development), often requiring upgrading of the existing equipment and leading to the focus on export-oriented manufacturing, especially in the automotive and engineering industries. New members have also seen an increasing amount of investment from EU-15 small and medium-size enterprises due to reducing political and economic risks after the enlargement. The main motives for investing in the new members have not changed much so far. These include high growth rates as well as favourable future forecasts (thus enabling market expansion), low unit labour costs (increasing efficiency), with the wages reaching one fifth of the EU-15 level with one third productivity,<sup>7</sup> lower corporate taxes (20% on average as compared to 31% in EU-15).<sup>8</sup> EU accession may also support improvement of the business environment (institutional framework).

On the other hand, investors in new member states still perceive persisting risks (see A.T. Kearney, 2005). These include underdeveloped infrastructure, high level of corruption and inevitable weakening low-cost advantage as a result of the increasing average income level. Economic and social costs of adjusting to the proposed EU reforms may be significant. New regulatory restrictions at the Communities level may decrease relative tax or labour cost advantages of new members for foreign investors and redirect them further to East and South (including the latest EU enlargement to Romania and Bulgaria).

---

<sup>7</sup> According to some estimates, the average wages in the new members will still be at 40-60% of the EU-15 level in 2020 (see UNCTAD, 2005, p. 87).

<sup>8</sup> The assessment of the tax burden must be more comprehensive and include other characteristics as well – e.g. the tax base, specific tax modes, see below.

16.4.2. Fragmentation of multinational value chain

The importance assigned to the (multinational) value chain structure reflects the position of EU members with less developed knowledge base combined with the strong presence of FDI business sector. While assessing the competitive advantage of these countries, the geographic fragmentation of the value chain must be considered, when different (qualitatively distinctive) segments are located in different countries. Less developed countries mostly host segments exploiting the advantages of low cost inputs. Location in countries at a similar or higher level of knowledge development is more motivated by the access to specific assets (e.g. new technology).<sup>9</sup> The quality of factor endowment (factor intensity) together with the level of technology capacities thus affect the depth of trade specialization as well as the motivation for the FDI inflows as a (possibly) important source of technology transfer.

As to the value chain structure differentiated in terms of input quality intensity, the production segment is usually the least developed. It can be based on imported technology, employing the staff trained for simple operational tasks (e.g. automated assembly lines). On the other hand, the complete chain includes not just the production itself but also the R&D activities and other knowledge-intensive segments. However, they usually remain located in the home country of foreign investors, where the knowledge base has already been appropriately developed.

The value chain fragmentation brings about a number of effects as to the **sources and direction of the competitive advantage**. As it has already been mentioned, the role of intra-industry trade becomes more significant. In this type of trade, similar products are exchanged, especially products in different production stages within multinational chains (as it is reflected in increasing volume of intra-company trade). If production costs increase, the pressure for moving labour-intensive segments into cheaper locations becomes stronger. Catching-up economy must therefore be able to replace them by activities that are more technology and skill intensive.

Such a transition, however, may be quite time and resource demanding. Specialization in **assembly of imported parts** (typical for countries with the advantage of relatively cheap labour force), even in industries classified as medium-high and high-technology intensive, has rather a very limited effect on technol-

---

<sup>9</sup> International production theories examine the motivations leading companies to expand their activities abroad (i.e. answer questions how, where and when). The reasons are divided based on the advantages they seek (in the OLI paradigm), whether they are unique assets as an income source (ownership advantage), possibility to internalize advantages resulted from the undertaken transactions exploiting economies of scale (internationalization advantage) or by making advantage of a particular location (localization advantage).

ogy capacity improvement in the host economy. The technology and skill intensities of these activities remain low, mostly not exceeding the averages in other industries. Their statistical export performance therefore do not as much reflects the ability to produce high-tech products but rather the specifics of (low-cost based) comparative advantage in the global production system. When foreign subsidiaries still develop their own R&D activities, the scope of knowledge spillovers in the host economy need to be assessed, as they are strongly affected by the linkages to the national innovation system and its key agents. These linkages mostly depend on a (relatively) small knowledge gap between domestic and foreign sectors, high level of human capital and the presence of technologically competent universities closely linked to the businesses.

#### 16.4.3. Foreign investment in knowledge-intensive activities

According to the World Investment Report (see UNCTAD, 2005), multinational companies dominate global R&D activities in both parent and host economies. Within the internationalization process, the newest trend is a fast increase in research activities of foreign subsidiaries in less developed countries in Asia and, to a lesser degree, in other regions, including the new EU members. A survey conducted as a part of the *FDI Confidence Index* focused on location preferences of foreign investors in R&D, based on groups of countries and the most important decision-making factors. Almost a half of global investors (48%) plan to increase R&D expenditures within the next three years, with only 3% planning their decrease. Almost three quarters of these increased expenditures will be directed to emerging countries of Asia and Eastern Europe, especially from North America and Western Europe (thus negatively affecting R&D expenditures in these countries). Poland and Russia are considered the most attractive countries for R&D investments in Eastern Europe. From the global perspective, both China and India lead the chart, leaving others far behind. (More than 40% of respondents plan to invest in these two countries).

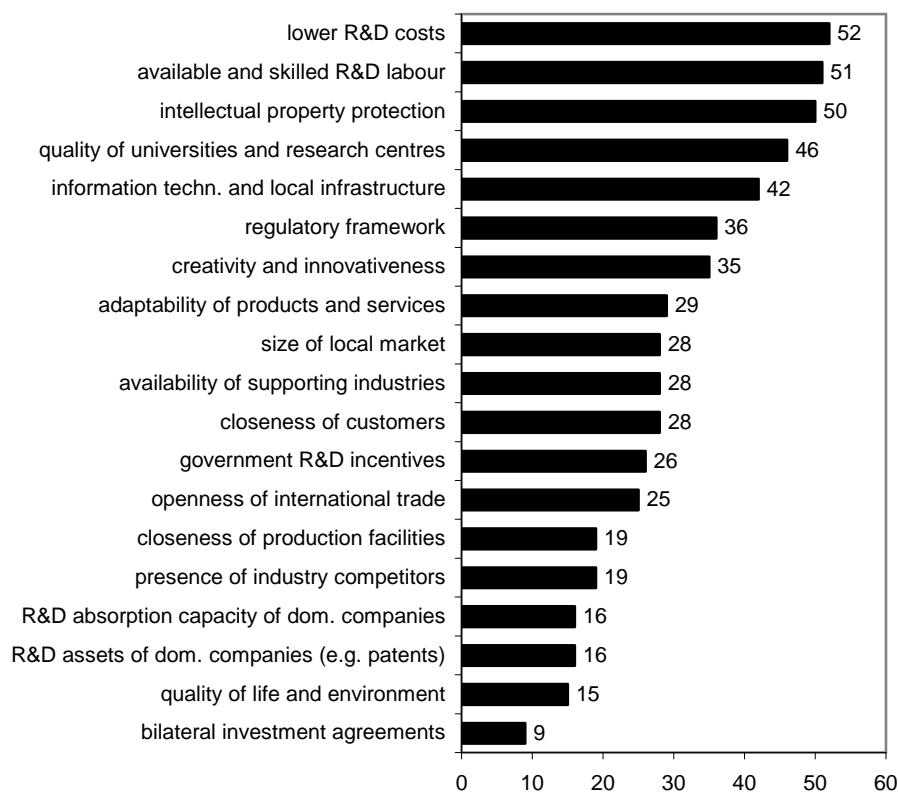

**Table 16.5. Shares of foreign investors planning to change regional focus of R&D expenditures, 2005 (%)**

	<b>Asia (excl. Japan)</b>	<b>Eastern Europe</b>	<b>North America</b>	<b>Western Europe</b>	<b>Latin America</b>	<b>Japan</b>	<b>Mid. East, Africa</b>
Increase	50	22	20	18	10	9	7

Investors assess the factors affecting the location of research and development investments ranked according to their importance. More than half of them stress the following three: lower R&D costs, availability, and quality of domestic workforce for R&D activities and a corresponding level of intellectual property protection. Figure 16.2 shows the importance of individual determinants of R&D investment location factors.

**Figure 16.2. Determinants of foreign investment in R&D (2005, % of respondents)**

In comparison with the EU average, the Czech Republic weaknesses in the key indicators of the **national innovation system** (see table 16.6) include especially the availability of human resources for R&D, intensity of links between the business sector and universities (and the intensity of their R&D activities) and in science and innovation output and the exploitation of venture capital. The relative expenditures on R&D as well as the protection of intellectual property are also lower.

**Table 16.6. Position of the Czech Republic and the key determinants of its innovation system**

	<b>R&amp;D activities</b>	<b>CR</b>	<b>EU-25</b>
R&D expenditure	R&D expenditure in % of GDP	1.3	1.9
	- Business sector	51.4	55.3
	- Government sector	41.8	34.0

#### 16.4.4. Knowledge-intensive activities of foreign companies

The importance of FDI subsidiaries for knowledge-intensive activities in the Czech Republic has been steadily increasing (see table 16.7). By 2004, they had already reached almost one half of R&D expenditures of the business sector.

**Table 16.7. Structure of manufacturing FDI (as at December 31, 2004) and the role of foreign companies in the Czech Republic in terms of technology intensity, 2002 (% of the business sector)**

	<b>High</b>	<b>Medium-high</b>	<b>Medium-low</b>	<b>Low</b>
Manufacturing FDI	14.5	33.2	32.4	19.9
Export	91.3	77.7	56.9	49.3
Import	88.0	84.5	48.5	64.1
Employment	47.0	41.3	26.0	20.9
Value added	48.8	52.3	35.8	42.3

Source: CNB, FDI Statistics, OECD – AFA Database 2005, 1.11.2006.

Out of the total new patent applications submitted to the European Patent Office (EPO) by Czech inventors in 2002, 55% were owned by foreign entities, i.e. they were carried out at subsidiaries of foreign companies. Based on the structure of manufacturing FDI at the end of 2004, medium-low-tech industries tend to prevail slightly (52.3%). Foreign companies have a significant part in the trade in high-tech products.

The participation of foreign subsidiaries in R&D activities (see table 16.8) is especially strong in manufacturing. The share of foreign subsidiaries in manufacturing R&D expenditures rose up to 65%, and up to 50% for researchers in 2004 (with the share in value added at 50%, and the share in employees at 33%). The share of foreign subsidiaries in R&D expenditures and the number of researchers are strongly industry-specific. The most apparent is the presence of foreign subsidiaries in the automotive industry (up to 95% of R&D expenditures and 83% of researchers in 2002) that belongs to the group of medium-high-tech industries. In this industry group, the R&D share of FDI companies significantly exceeds their share in value added.

**Table 16.8. Business sector R&D expenditures (in CZK million)**

Manufacturing		15-37	100,0	100,0	6,5	2,2	41,4	59,0

Notes: R&D intensity for OECD expressed by the median for 12 developed members in 1999.

Source: OECD (2005), p. 182, 207-208, CZSO – Science and technology indicators (2004), p. 269 (updated at 1.8.2006), OECD – AFA Database, 1.11.2006, modified.

The R&D intensity in the automotive industry (and, to a lesser degree in other transport equipment) comes at least closer to the value justifying its classification as a medium-high-tech industry. The most extreme contrast between these two viewpoints is apparent in the office and computer equipment (classified as high-tech industries in developed countries), in respect to which the R&D intensity in the Czech Republic reaches the values comparable to food or wood industries. To conclude, we may say that in terms of R&D intensity there are yet no industries in the Czech Republic reaching high-tech intensity.

Based on the **actual R&D intensity**, only pharmaceutical industry, the aforementioned automotive industry, and possibly other transport appliances could be placed in the medium-high-tech group in the Czech Republic. All other manufacturing industries fall under the medium-low or low-tech category. In this

adjusted definition of technology groups, the share of medium-high and high-tech industries in Czech exports would reach only 18.6% in 2003 (in comparison with the reported value of 59.4%).

According to the survey on **innovation activities** for the period of 2002 – 2003, 41% of foreign subsidiaries (companies located in the Czech Republic with the HQ abroad) carry out innovation activities as compared to 24% of Czech companies (see table 16.10). In comparison to innovation performance of the total sample, foreign subsidiaries show up higher values in manufacturing, especially then in the food industry, rubber and plastics, electrical and optical appliances. As for services, innovation results of foreign subsidiaries are significantly better in all industries. However, innovation intensity in foreign subsidiaries is only slightly higher compared to the total sample.

**Table 16.10. Share of innovative companies (INNO) and innovation intensity (INT) in the Czech Republic, 2002-03**

	Total		Foreign affiliates	
	INNO	INT	INNO	INT
Total	25.9	1.6	41.1	1.7

## 16.5. Conclusions

In terms of structural globalization characteristics, the export dynamics to the EU countries have increased significantly over the last few years following

strong inflows of foreign direct investment to the Czech Republic. At the same time, the export structure has been changing as well, with engineering, and the automotive industry especially, gaining an ever increasing share. Pro-export effect of foreign investments started to prevail over the influence of imports of investment goods in the first stage of the FDI life cycle. The strong geographical concentration of trade on Germany may present a potential trade balance problem, as may product over-specialization in industries related to automotive production. Within EU-15 imports, machinery and transport vehicles are dominant, while the imports from the new EU members include predominantly products with lower technology intensity.

Within the last ten years, the trade structure of new EU members, including the Czech Republic, has shifted significantly in favour of technology more intensive products that represent approximately 60% of imports to EU countries. Medium-high-tech industries (especially the automotive industry) have the highest contribution toward trade balance, with the contribution of high-tech industries still being negative, though gradually improving. These industry groups have also the highest share of products for export. However, since the predominant part of the production is assembly-based, value added remains relatively low (especially in the office and computer equipment).

The importance of foreign companies in the total R&D expenditures has been recently significantly growing especially due to changes in the ownership structure of large companies. The share of value added in knowledge-based activities still remains relatively low when compared to developed countries, both in terms of R&D intensity and quality-intensity of employment, a fact that is also reflected in low economic performance achievements (especially in production). This is predominantly the case of the industries that are traditionally classified as high-tech. The combination of a high level of foreign direct investments and the low quality of value chain requires an intensive policy support expanding the supply of domestic knowledge-intensive inputs and developing infrastructure of the national innovation system.

In terms of foreign direct investments in R&D activities, the region of Central and Eastern Europe receives very positive ratings by investors, with almost one quarter expecting an increase in R&D expenditures (however, for Asian countries almost one half expect this development). As far as the location determinants for R&D expenditures are concerned, the Czech Republic lags behind especially in the availability of human resources for research, in the intensity of linkages between the business sector and universities, the level of scientific and innovation output and in exploitation of venture capital. Foreign companies in the Czech Republic play an increasingly important role in knowledge-intensive activities, covering almost a half of business sector R&D expenditures, with this share growing up to 65% in manufacturing (yet in services, it is less than 1/4).
